A skull of a woman from a heathen grave at Hólaskógi in Thjórsárdal. It is probable that a dental infection in the upper jaw was the cause of her death.

Photo and text of display at
Iceland's National Museum in Reykjavik

Comparison between acute and chronic inflammation:

	Acute	Chronic
<i>Causative agent</i>	Pathogens, injured tissues	Persistent acute inflammation due to non-degradable pathogens, persistent foreign bodies, or autoimmune reactions
<i>Major cells involved</i>	Neutrophils, mononuclear cells (monocytes, macrophages)	Mononuclear cells (monocytes, macrophages, lymphocytes, plasma cells), fibroblasts
<i>Primary mediators</i>	Vasoactive amines, eicosanoids	IFN- γ and other cytokines, growth factors, reactive oxygen species, hydrolytic enzymes
<i>Onset</i>	Immediate	Delayed
<i>Duration</i>	Few days	Up to many months, or years
<i>Outcomes</i>	Resolution, abscess formation, chronic inflammation	Tissue destruction, fibrosis

Comparison between acute and chronic inflammation:

Comparison between acute and chronic inflammation:

	Acute	Chronic
<i>Primary mediators</i>	Vasoactive amines, eicosanoids (In biochemistry, eicosanoids are signaling molecules made by oxygenation of twenty-carbon essential fatty acids, (EFAs).	IFN- γ and other cytokines, growth factors, reactive oxygen species, hydrolytic enzymes

Name	Produced by	Description
<u>Bradykinin</u>	<u>Kinin system</u>	A vasoactive protein which is able to induce vasodilation, increase vascular permeability, cause smooth muscle contraction, and induce pain.
<u>C3</u>	<u>Complement system</u>	Cleaves to produce C3a and C3b. C3a stimulates histamine release by mast cells, thereby producing vasodilation. C3b is able to bind to bacterial cell walls and act as an opsonin, which marks the invader as a target for phagocytosis.
<u>C5a</u>	<u>Complement system</u>	Stimulates histamine release by mast cells, thereby producing vasodilation. It is also able to act as a chemoattractant to direct cells via chemotaxis to the site of inflammation.

Name	Produced by	Description
<u>Factor XII (Hageman Factor)</u>	<u>Liver</u>	A protein which circulates inactively, until activated by collagen, platelets, or exposed basement membranes via conformational change. When activated, it in turn is able to activate three plasma systems involved in inflammation: the kinin system, fibrinolysis system, and coagulation system.
<u>Membrane attack complex</u>	<u>Complement system</u>	A complex of the complement proteins C5b, C6, C7, C8, and multiple units of C9. The combination and activation of this range of complement proteins forms the <i>membrane attack complex</i> , which is able to insert into bacterial cell walls and causes cell lysis with ensuing death.
<u>Plasmin</u>	<u>Fibrinolysis system</u>	Able to break down fibrin clots, cleave complement protein C3, and activate Factor XII.
<u>Thrombin</u>	<u>Coagulation system</u>	Cleaves the soluble plasma protein fibrinogen to produce insoluble fibrin, which aggregates to form a blood clot. Thrombin can also bind to cells via the PAR1 receptor to trigger several other inflammatory responses, such as production of chemokines and nitric oxide.

Vital, inflamed: reversible-irreversible pulpitis

Microabscesses can heal
Mjør & Tronstad 1972

Fig. 1.3. Breaks in the muco-cutaneous barrier associated with teeth. (a) Attrition (A), abrasion or trauma exposes the pulp. (b) Dental caries (C) reaches the pulp with subsequent infection of the pulp and periapical tissues. (c) Dental plaque (P) penetrates the gingival cuff and bacteria invade the gingival and periodontal tissues.

Periapical diagnoses

- **Transient AP**
- **Incipient AP**
- **Condensing AP**
- **Acute apical periodontitis AAP**
- **Chronic apical periodontitis CAP**
 - **Dental granuloma**
 - **Cyst: true cyst or bay cyst**
- **Exacerbating CAP**

PU.1 regulates cytokine-dependent proliferation and differentiation of granulocyte/macrophage progenitors

A mononuclear phagocyte colony-stimulating factor (M-CSF) synthesized by mesenchymal cells

Receptor activator of nuclear factor- B ligand (RANKL) is a critical cytokine for osteoclast differentiation and activation and an essential regulator of osteoblast-osteoclast cross-talks (4). RANKL activates its receptor RANK, which is located on osteoclastic lineage cells, and this interaction is prevented by osteoprotegerin (OPG), which acts as an endogenous receptor antagonist and blocks the effects of RANKL (4). While RANKL enhances bone resorption and bone loss and promotes osteoporosis, OPG has opposite effects (5).

Crit Rev Oral Biol Med. 2004;15(2):64-81. NEW MOLECULES IN THE TUMOR NECROSIS FACTOR LIGAND AND RECEPTOR SUPERFAMILIES WITH IMPORTANCE FOR PHYSIOLOGICAL AND PATHOLOGICAL BONE RESORPTION. [Lerner UH.](#)

Hvordan oppstår odonto/osteoklaster?

- Osteoclasts formation requires the presence of RANK ligand (receptor activator of nuclear factor $\kappa\beta$) and M-CSF (Macrophage colony-stimulating factor). These membrane bound proteins are produced by neighbouring stromal cells and osteoblasts; thus requiring direct contact between these cells and osteoclast precursors.
- M-CSF acts through its receptor on the osteoclast [precursor], c-fms (colony stimulating factor 1 receptor), a transmembrane tyrosine kinase-receptor, leading to secondary messenger activation of tyrosine kinase Src. Both of these molecules are necessary for osteoclastogenesis and are widely involved in the differentiation of monocyte/macrophage derived cells.

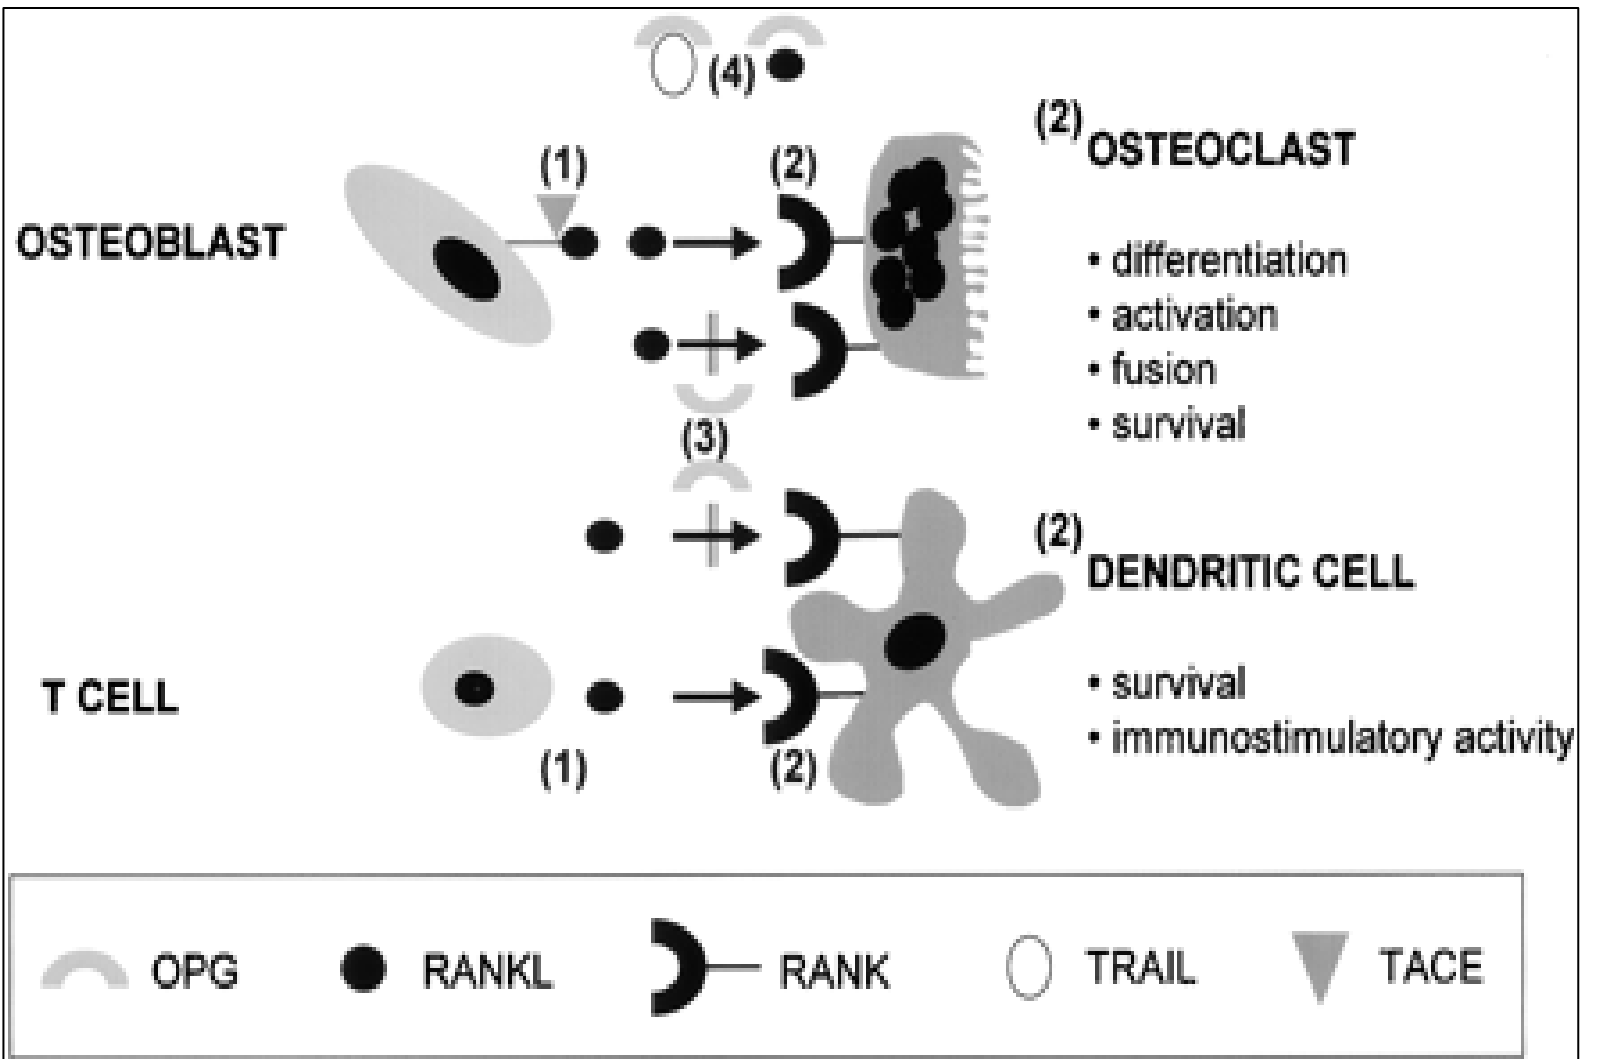

Hvordan oppstår odonto/osteoklaster?

- RANKL is a member of the tumour necrosis family (TNF), and is essential in osteoclastogenesis. RANKL knockout mice exhibit a phenotype of osteopetrosis and defects of tooth eruption, along with an absence or deficiency of osteoclasts. RANKL activates NF- κ B (nuclear factor- κ B) and NFATc1 (nuclear factor of activated t cells, cytoplasmic, calcineurin-dependent 1) through RANK. NF- κ B activation is stimulated almost immediately after RANKL-RANK interaction occurs, and is not upregulated. NFATc1 stimulation, however, begins ~24-48 hours after binding occurs and its expression has been shown to be RANKL dependent.
- Osteoclast differentiation is inhibited[/regulated] by osteoprotegerin (OPG), which binds to RANKL thereby preventing interaction with RANK.

Schoppet M, Preissner KT, Hofbauer LC. RANK ligand and osteoprotegerin: paracrine regulators of bone metabolism and vascular function. *Arterioscler Thromb Vasc Biol.* 2002 Apr 1;22(4):549-53. Review.

Figure 2. Mode of action and biological effects of RANKL, RANK, and OPG on bone metabolism and the immune system. (1) RANKL is expressed by osteoblastic lineage cells (cell-bound RANKL) and activated T lymphocytes (soluble RANKL). A truncated ectodomain form of RANKL is derived from the cell-bound form after cleavage by the enzyme TACE. (2) All three RANKL variants stimulate their specific receptor, RANK, which is located on osteoclastic and dendritic cells and thus modulate various biological functions. (3) OPG is secreted by osteoblastic lineage and other cells and acts as a soluble receptor antagonist which neutralizes RANKL (black), and thus, prevents RANKL-RANK interaction. (4) OPG also blocks the pro-apoptotic cytokine TRAIL (white).
